[Title of Document] ABSTRACT

[Abstract]

[Problem] To provide a transparent laminate which satisfies all the electromagnetic wave shielding property, near-infrared cutting property, visible light transmitting property and visible light low-reflecting property, and which exhibits a color tone of neutral gray with little dependence of the transmittance of the transparent laminate on wavelengths in a visible light range.

[Solving Means] In a transparent laminate in which  $n$  thin-film units ( $n = 3$  or  $4$ ) are laminated unit by unit successively on a surface of a substrate 1, and a high-refractive-index transparent thin film 2D is formed on a surface of the laminate of the  $n$  thin-film units, each of the  $n$  thin-film units consisting of a high-refractive-index thin film 2A and a silver transparent conductor thin film 3A, when the silver transparent conductor thin films (3A-3C) are formed by a vacuum dry process, the temperature  $T$  (K) of the transparent substrate 1 at the time of film formation is set to be in a range  $340 \leq T \leq 410$ , whereby the transparent having a standard deviation of visible light transmittance which is not larger than 5 % in a wave range of from 450 to 650 nm can be produced.
